

Session 1

The Accessibility tree and ARIA

Slide instructions

SPACEBAR to **move forward** through slides.

SHIFT & **SPACEBAR** to **move backwards** through slides.

LEFT ARROW & **RIGHT ARROW** to **move through sections**.

ESC to **see overview** and **ESC** again to exit.

F to **enter presentation mode** and **ESC** to exit.

Introduction

A developer's role in accessibility is to make **flexible, transformable** websites.

Flexible sites allow people to use any device, with any setting they need.

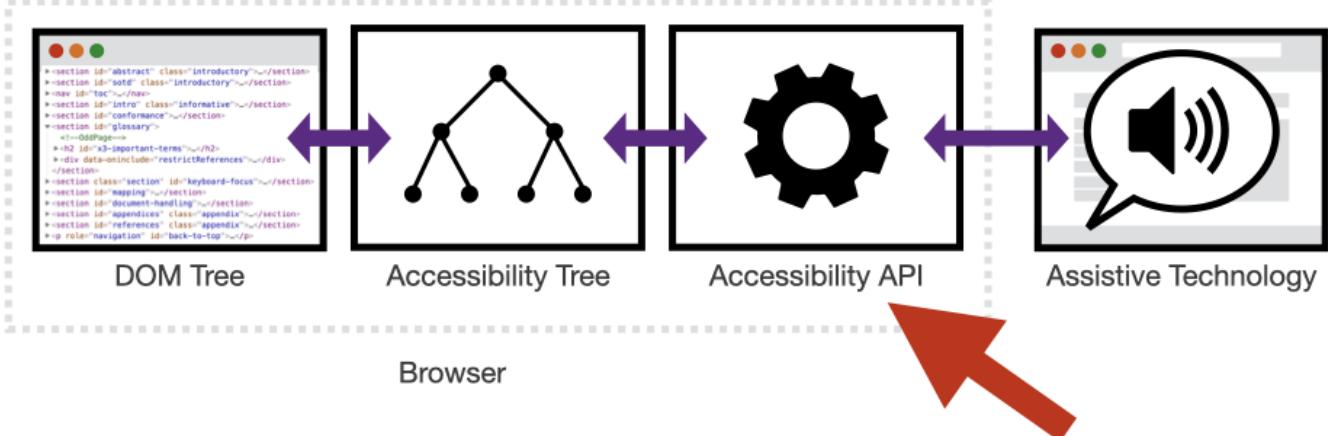

We can provide **sensible defaults** without blocking anyones less common preferences.

Assistive technology can **transform** our site into a format that works for a specific user group.

We need to make sure all the information about a site is **available in the code**.

Accessibility APIs

Accessibility APIs **communicate information about the user interface** from the browser to the assistive technology.

There have been many Accessibility APIs released over the years, all **building on and improving previous versions.**

Year	API	For
1997	<u>Microsoft Active Accessibility (MSAA)</u>	Windows 95
1998	<u>IAccessible</u>	Cross platform
2001	<u>Assistive Technology Service Provider Interface (AT-SPI)</u>	Linux OS
2002	<u>NSAccessibility</u>	Mac OS 10.2
2007	<u>User Interface Automation (UIA)</u>	Windows 7
2007	<u>IAccessible2</u>	Windows and Linux
2009	<u>UI Accessibility API</u>	iOS 3

Browsers generally support one or more of the available accessibility APIs **for the platform they're running on.**

Windows:

- Firefox, Chrome and Opera support: MSAA/*IAccessible* and *IAccessible2*.
- Edge supports MSAA/*IAccessible* and *UIAExpress*.

OSX:

- Safari, Firefox and Chrome support: *NSAccessibility*.

iOS:

- Safari, Firefox and Chrome support *UIAccessibility*.

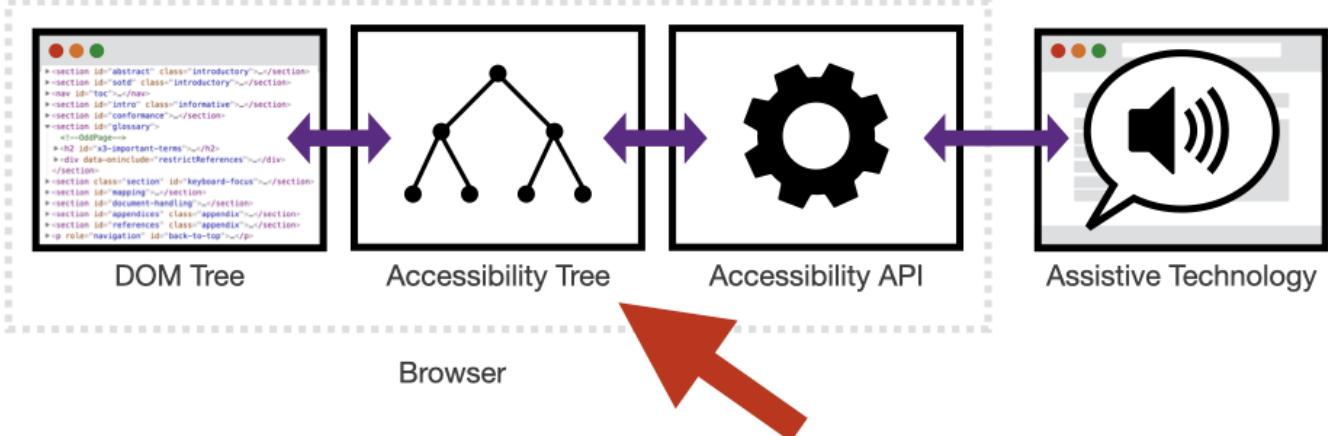

Each browser may have a different Accessibility API, which means **you may get slightly different results**.

When testing new components, you have to test across
a range of different combinations.

AT	Browsers
Windows: NVDA	Chrome, Firefox, Edge
Windows: JAWS	Chrome, Firefox, Edge
OSX: VoiceOver	Chrome, Firefox, Safari
iOS: VoiceOver	Chrome, Safari
Android: TalkBack	Chrome

Any questions or comments?

Accessibility Tree

The browser uses the DOM, along with further information derived from CSS, to generate an **Accessibility Tree**.

This information is **passed to the relevant accessibility APIs** associated with the browser / operating system.

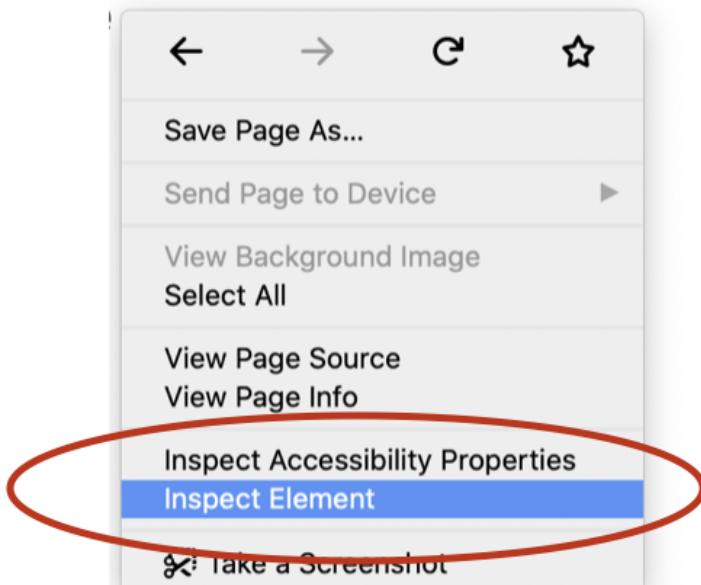

This accessibility tree exposes **information on specific elements** to assistive technologies via the accessibility API.

Information includes:

- The **role, name and state** of each object in the content.
- How each object **relates to other objects** in the content.

Each browser **will produce a unique accessibility tree** due to their specific combination of source code and accessibility API.

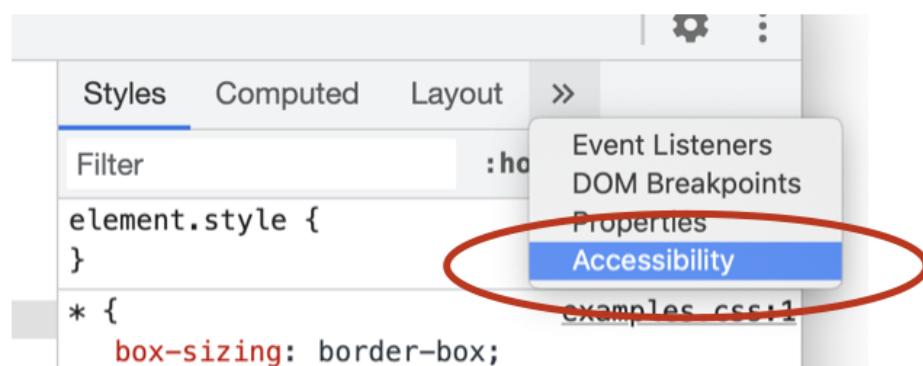

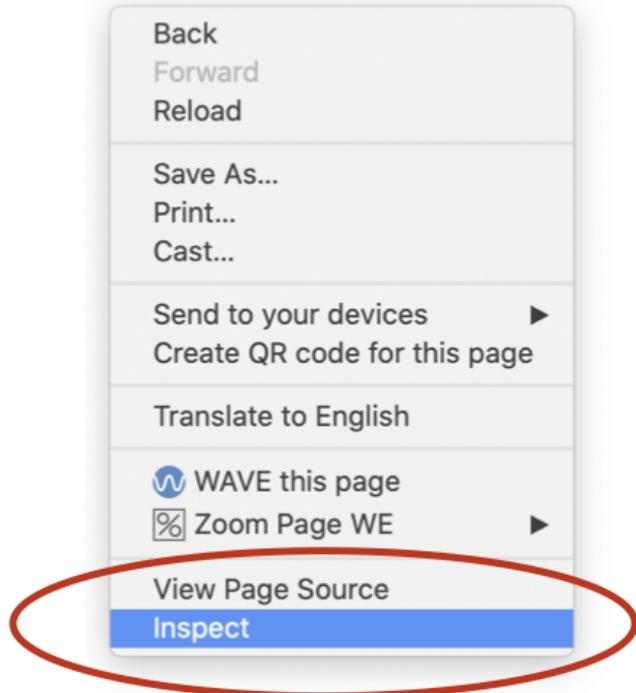

Accessing the Accessibility Tree in Firefox

The screenshot shows the Chrome Developer Tools Accessibility panel. At the top, there are tabs for Inspector, Console, Debugger, Network, Style Editor, Performance, Memory, Storage, Accessibility (which is highlighted and circled in red), and more. Below the tabs, there are dropdowns for 'Check for issues' (set to 'None') and 'Simulate' (set to 'None'). A 'beta' button and a 'Show Tabbing Order' checkbox are also present.

The main area displays the accessibility tree. A table has two columns: 'Role' and 'Name'. Under 'Role', it lists 'document'. Under 'Name', it lists 'input where \"title\" should be accessible name'. To the right of the table, there are sections for 'Checks' (showing 'No checks for this node.') and 'Properties' (listing various attributes like name, role, value, DOMNode, description, keyboardShortcut, childCount, indexInParent, states, relations, and attributes). The 'name' property is highlighted in pink.

Accessing the Accessibility Tree in Chrome

Contents: "What are mammals?"
title: Not specified
Role: heading
Level: 1

▼ Source Order Viewer

No source order information available

The screenshot shows the Chrome DevTools Elements tab open, displaying the accessibility tree for a web page. The tree structure is as follows:

- RootWebArea "Exercise page for keyboard and screen reader use" **focusable: true**
 - banner ""
 - StaticText "Exercise page for keyboard and screen reader use"
 - navigation ""
 - list ""
 - main "What are mammals?"
 - heading "What are mammals?"
 - StaticText "What are mammals?"
 - paragraph ""
 - paragraph ""
 - heading "Classification"
 - paragraph ""
 - paragraph ""
 - heading "Definitions"
 - paragraph ""
 - paragraph ""
 - heading "McKenna/Bell classification"
 - paragraph ""
 - heading "Types of mammals"
 - table "Land mammals"
 - table "Aquatic mammals"

Breaking down Chrome's Accessibility Tree

Chrome's "Accessibility" tab has **three key areas**:

- accessibility tree,
- ARIA attributes, and
- computed properties.

As you inspect an element in the DOM, the relationships between each element are presented in the **Accessibility Tree tab**.

Styles Computed Accessibility »

▼ Accessibility Tree

 ▶ table "Aquatic mammals"

As you inspect an element in the DOM, any relevant ARIA attributes are presented in the **ARIA Attributes tab**.

As you inspect an element in the DOM, all the computed properties of that element are presented in the **Computed Properties tab**.

The screenshot shows a developer tools sidebar with several tabs at the top: Styles, Computed, Accessibility, and a double-right arrow. The 'Computed' tab is active, indicated by a blue underline. Below the tabs is a list of sections: 'Accessibility Tree', 'ARIA Attributes', and 'Computed Properties'. The 'Computed Properties' section is expanded, showing a list of properties for an element named 'Cat'. The 'aria-labelledby' property is expanded, showing its value is 'Cat', which is also highlighted in red. Other properties listed include 'aria-label', 'From label', 'Contents', 'title', 'Description', 'Role', 'Invalid user entry', and 'Focusable'. A red oval highlights the 'Computed Properties' section.

Computed Properties

Any questions or comments?

**Exercise: Viewing the
Accessibility Tree**

Accessing the exercise:

<https://russmaxdesign.github.io/exercise/.>

Browsers use the DOM tree to create a second tree, called the **accessibility tree**.

1. Heading role and level

Inspect the “**What are mammals?**” heading. What is this element’s **role** and **level** in the accessibility panel?

Mammals

[What are mammals?](#) [Classification](#) [Definitions](#) [McKenna/Bell](#) [Molecular](#)

What are mammals?

Mammals are the vertebrates within the class *Mammalia*, a clade of *endothermic amniotes* distinguished from reptiles (including birds) by the possession of a neocortex (a region of the brain), hair, three middle ear bones, and mammary glands. Females of all mammal species nurse their young with milk, secreted from the mammary glands.

[Find out more](#) (1)

Classification

Mammal classification has been through several iterations since Carl Linnaeus initially defined the class. No classification system is universally accepted; McKenna & Bell (1997) and Wilson & Reader (2005) provide useful recent compendiums.^[1] George Gaylord Simpson's "Principles of Classification and a Classification of Mammals" (AMNH Bulletin v. 85, 1945) provides systematics of mammal origins and relationships

[Find out more about classifications](#) (2)

Definitions

If Mammalia is considered as the crown group, its origin can be roughly dated as the first known appearance of animals more closely related to some extant mammals than to others. *Ambondro* is more closely related to monotremes than to therian mammals while *Amphilestes* and *Amphitherium* are more closely related to the therians; as fossils of all three genera are dated about 167 million years ago in the Middle Jurassic, this is a reasonable estimate for the appearance of the crown group.

Checked: true

Labeled by: label

6. Changing the semantics

Add `role="button"` to an `<h2>` element and **check the accessibility tree**.

As you can see, the `role: heading` has now been replaced with `role: button`.

This shows how we can **completely change the nature of an element** in the accessibility tree - which is then communicated to assistive technologies.

A wide range of properties

There are a wide range of possible properties that can be presented as part of the accessibility tree, **depending on the element being inspected.**

Some of the **key accessibility tree properties include:**

```
Name: [ accessible name as a text string ]
Role: [ pre-defined list of roles ]
Description: [ description as a text string ]
Value: [ current value as a text string ]
Required: true | false
Expanded: true | false
Checked: true | false
Disabled: true | false
Described by: [element #id]
Labeled by: [element #id]
```

Any questions or comments?

Quiz: Guessing some terms

Does anyone know what the terms “**WAI**” and “**ARIA**” stand for?

What is ARIA?

Web Accessibility Initiative (WAI)

WAI is a working group that develops standards and support materials to help implement accessibility.

Accessible Rich Internet Applications (ARIA)

ARIA is a standard that defines a way to make websites and web apps more accessible to people with disabilities.

ARIA defines how to **make websites more accessible**, focussing on:

- Dynamically injected content.
- Non-native widgets/components.

WAI-ARIA 1.0 was published as a completed **W3C Recommendation on 20 March 2014.**

WAI-ARIA 1.1 was published as a completed **W3C Recommendation** on 14 December 2017.

WAI-ARIA 1.2 was published as a completed **W3C Working Draft** 18 December 2019. This means it is still not the official standard yet!

Any questions or comments?

How does ARIA work?

You could think of ARIA as the **bridge** between the HTML we have now, and the HTML we wish we had.

But how does it work? ARIA can be defined in **three simple statements**:

- ARIA is a series of custom HTML attributes.
- These attributes can be used to change and augment the accessibility tree.
- They provide additional information to assistive technologies.

ARIA can be used to change and augment the accessibility tree **in the following six ways:**

1. Add or modify semantics to the accessibility tree

i.e. adding semantics to generic elements via the role attribute.

```
<div role="button"></div>
```

2. Apply states to the accessibility tree

i.e. informing assistive technologies of a widget's current state.

```
<button aria-expanded="true"></button>
```

3. Provide or improve accessible names in the accessibility tree

i.e. adding additional labelling to elements.

```
<button aria-label="Close modal"></button>
```

4. Provide descriptions to the accessibility tree

i.e. adding descriptions to elements.

```
<input type="text" aria-describedby="a1">  
<span id="a1">Error message</span>
```

5. Establish relationships in the accessibility tree

i.e. informing assistive technologies of the relationships between specific elements, that may not be possible via the DOM.

```
<button role="tab" aria-controls="a1"></button>
<div role="tabpanel" id="a1"></div>
```

6. Informing assistive technologies about possible changes to the DOM

i.e. Defining a region as “live” because it may change.

```
<div aria-live="polite"></div>
```

ARIA does not do...

ARIA does not do any of the following:

1. modify an element's visual appearance
2. modify the element's behaviour
3. add focusability, or
4. add keyboard functionality.

ARIA roles, states and properties

ARIA attributes are **broken down into three categories:**

- Roles
- States
- Properties

ARIA roles are HTML attributes that are added to elements using:

`role="[role-type]"`

ARIA roles can be used to **add or change the semantic meaning** of HTML elements in the accessibility tree.

For example: *Is the element a menu, slider, spinner, progress bar?*

```
<div role="tabpanel"></div>
```

A list of all roles, including how they have changed in different versions of ARIA.

ARIA states and properties are HTML attributes that are added to elements using:

`aria-[state|property]=[property-type]`

ARIA states **define the current state** of HTML elements in the accessibility tree.

For example: *Is the element checked or disabled?*

```
<input aria-disabled="true" type="text">
```

ARIA properties **define the purpose or relationships** of HTML elements in the accessibility tree.

For example: *Does the element have a description? Does the element interact with other elements?*

```
<input aria-describedby="format">
<span id="format">(dd/mm/yyyy)</span>
```

Browser support and complexity

The **different accessibility APIs** mean that browsers and platforms can interpret your name, role and property information differently.

Each brand of assistive technology will prioritise different experiences for their users.

A11ySupport.io and HTML test cases have cross-browser support information for ARIA.

Any questions or comments?

**Exercise: Creating a
fake checkbox**

Accessing the exercise:

- Open [Fake checkbox - start](#) at CodePen.io.
- View [Fake checkbox - finished](#) to check your results.

Imagine you have to make a checkbox group, but you have to use `<div>` elements **instead of native checkboxes**.

As you will see:

- **Some basic JavaScript** is already in place.
- **Keyboard focus** is in place via `tabindex="0"`.

However, this widget is completely **inaccessible to assistive technologies**. Let's look at it in the accessibility panel.

- The elements have **no role defined**.
- The elements have **no checked state defined**.
- The `<h3>` heading is **not programmatically associated** with the checkbox group.

Step 1:

Add `role="checkbox"` to each of the fake checkboxes.

```
<div
  class="checkbox"
  tabindex="0"
  role="checkbox"
>
  Lettuce
</div>
```

```
<div
  class="checkbox"
  tabindex="0"
  role="checkbox"
>
  Tomato
</div>
```

```
<div
  class="checkbox"
  tabindex="0"
  role="checkbox"
>
  Mustard
</div>
```

Step 2:

- Add `aria-checked="true"` to the first fake checkbox.
- Add `aria-checked="false"` to other fake checkboxes.

```
<div
  class="checkbox"
  tabindex="0"
  role="checkbox"
  aria-checked="true"
>
  Lettuce
</div>
```

```
<div
  class="checkbox"
  tabindex="0"
  role="checkbox"
  aria-checked="false"
>
  Tomato
</div>
```

```
<div
  class="checkbox"
  tabindex="0"
  role="checkbox"
  aria-checked="false"
>
  Mustard
</div>
```

If we inspect any of the fake checkboxes in the accessibility tree, **they now have roles and states**.

▼ Name: "Lettuce"
aria-labelledby: Not specified
aria-label: Not specified
Contents: "Lettuce"
title: Not specified
Role: checkbox
Focusable: true
Focused: true
Checked: true

Step 3:

Add `role="group"` to the parent container so that we can create a fake `<fieldset>`.

```
<div  
  role="group"  
>  
</div>
```

Step 4:

Add `aria-labelledby="group-label"` to the parent container so we can give it an accessible name.

```
<div  
  role="group"  
  aria-labelledby="group-label"  
>  
</div>
```

Step 5:

Add `id="group-label"` to the `<h3>` element. Now it will operate like a fake `<legend>`.

```
<h3 id="group-label">Choose some toppings</h3>
```

If we inspect the parent container in the accessibility tree, **it now has an accessible name and a role.**

```
▼ Name: "Choose some toppings"
  ▼ aria-labelledby.
    h3#group-label "Choose some toppings"
    aria-label: Not specified
    title: Not specified
  Role: group
  Labeled by: h3#group-label
```

This is a quick example to show how ARIA is used to **augment the accessibility tree** to help assistive technologies.

Forms and assistive technologies

Screen reader users can navigate through a page using **a range of different methods.**

However, when some screen readers reach a form element they switch from “**Browse mode**” to “**Forms mode**”.

In “Forms mode”, the **only way to navigate through the form fields** is via the **TAB** key.

In this mode, focus will move from one focusable element to the next. Any elements that do not receive focus **will be ignored**.

For this reason, we need to **programmatically associate** all relevant information to the form field.

This makes sure that all the relevant information is
announced when the form field is in focus.

Relevant information could include:

- The form field's label.
- Additional information to help users fill in the form field.
- Error messages associated with the form field.
- If the form field is required.

For the rest of this session, we will focus on:

- How to **create labels for form fields** - using accessible names and visible text labels.
- How to **programmatically associate labels and additional information** with form fields.

In the following sessions, we'll look at programmatically associating **required fields and error messages** with form controls.

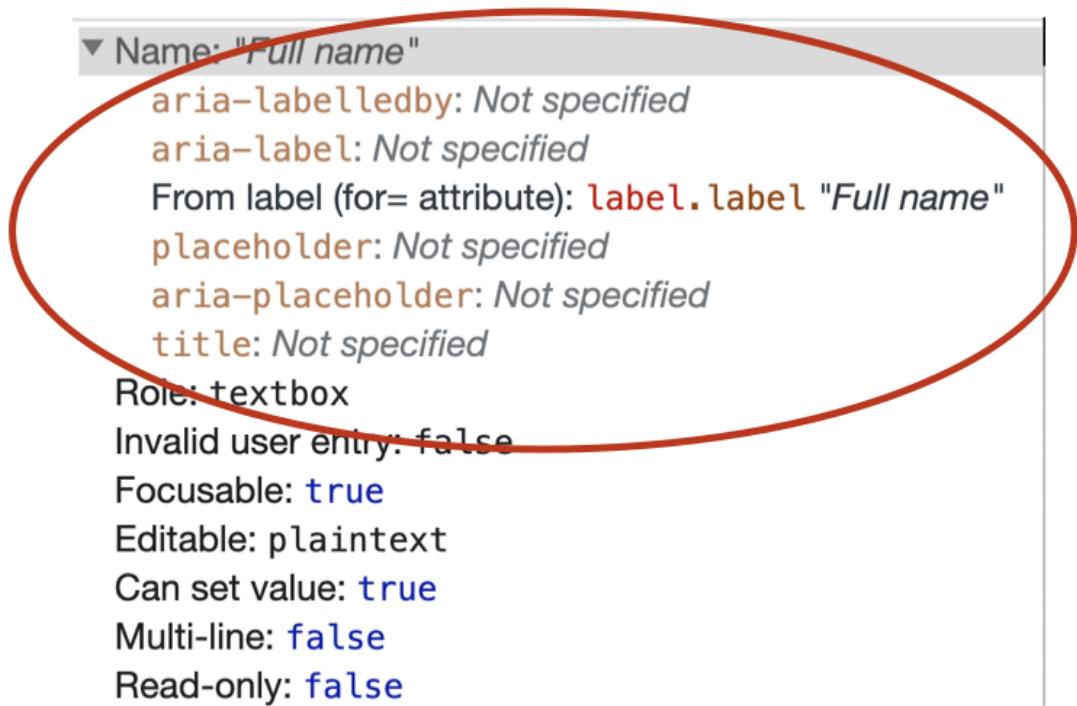

Accessible names

Accessible names are names given to elements in the accessibility tree.

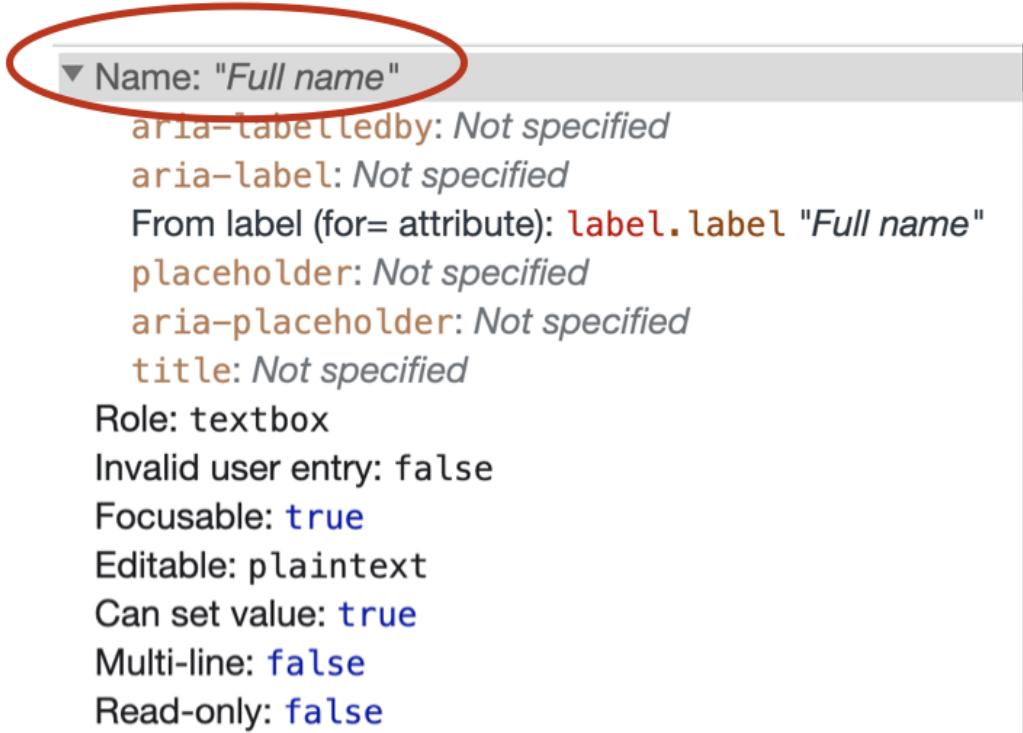

Accessible names are very important for assistive technology users as they **help to identify elements within the accessibility tree.**

Accessible names are defined as **text strings**.

Chrome's accessibility tree shows **all the possible options** that could be used to provide the accessible name.

It also displays the **final computed accessible name** as a text string.

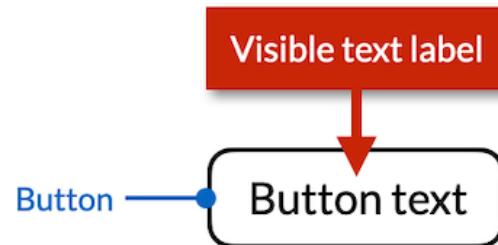

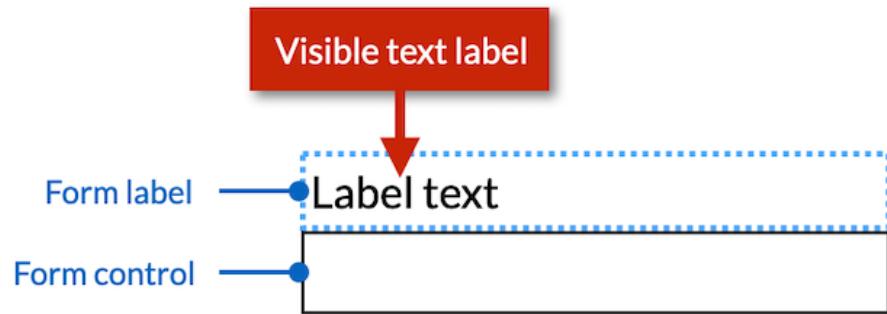

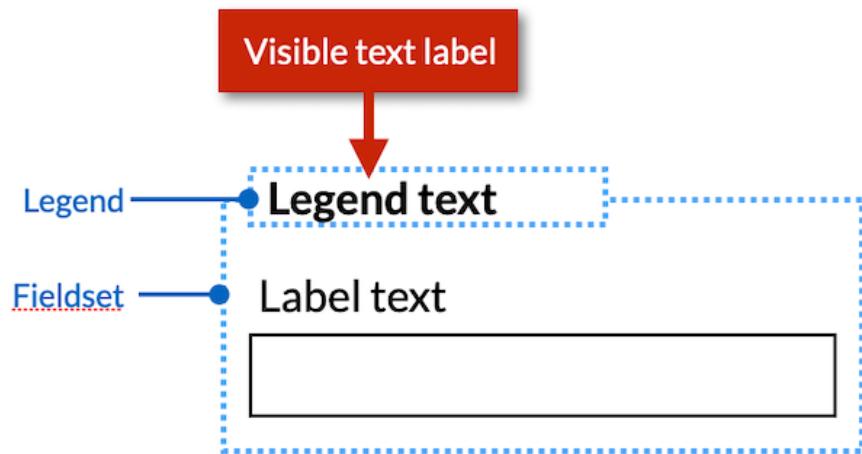

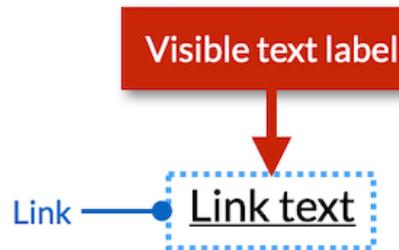

The screenshot shows a developer tools element inspector for a text input field. The 'Name' property is highlighted with a red oval, displaying the value "Full name". Other properties listed include: aria-labelledby: Not specified; aria-label: Not specified; From label (for= attribute): label.label "Full name"; placeholder: Not specified; aria-placeholder: Not specified; title: Not specified; Role: textbox; Invalid user entry: false; Focusable: true; Editable: plaintext; Can set value: true; Multi-line: false; Read-only: false.

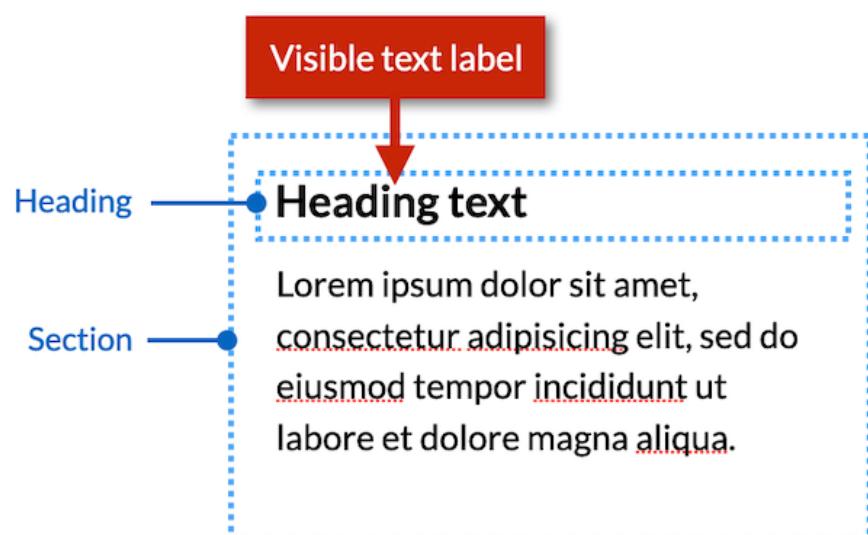

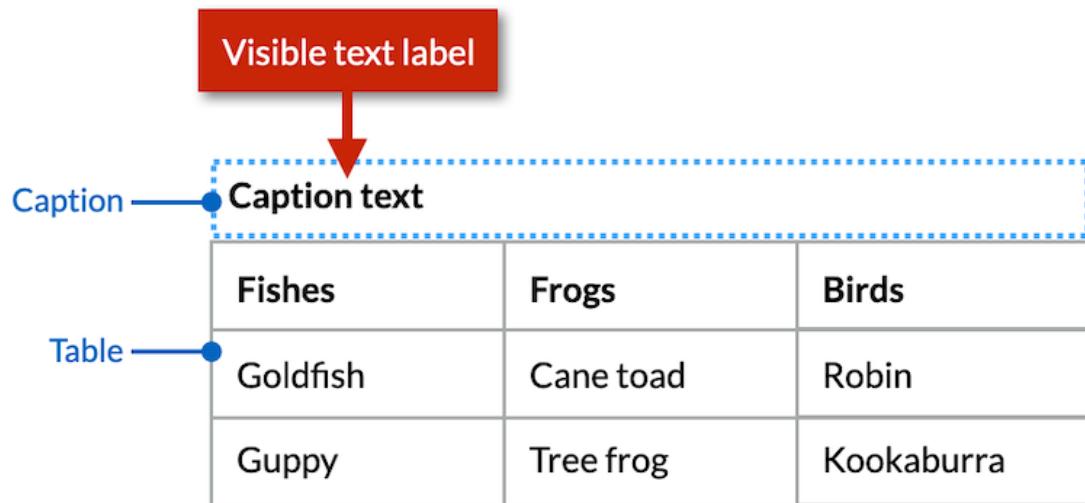

- ▼ Name: "Full name"
- aria-labelledby: Not specified
- aria-label: Not specified
- From label (for= attribute): label.label "Full name"
- placeholder: Not specified
- aria-placeholder: Not specified
- title: Not specified
- Role: textbox
- Invalid user entry: false
- Focusable: true
- Editable: plaintext
- Can set value: true
- Multi-line: false
- Read-only: false

Visible text labels

A visible text label is a label that is **presented on-screen as text**. Visible labels can include:

Do accessible names and visible text labels have to match?

In some cases, the accessibility name **matches the visible text label**.

```
<button>Save</button>
```

Save

Visible text label = "Save"

The screenshot shows a browser's developer tools with the 'Elements' tab selected. The page source code is visible on the left, showing a single button element with the text 'Save'. On the right, the 'Accessibility' panel is open, showing the 'Computed Properties' section. A red circle highlights the 'Name: "Save"' entry, and a red arrow points from the visible text label 'Save' in the main view to this entry in the accessibility panel.

Computed Properties
Name: "Save"
aria-labelledby: Not specified
aria-label: Not specified
From label: Not specified
Contents: "Save"
title: Not specified
Role: button
Invalid user entry: false
Focusable: true

```
<label for="aaa">First name</label>
<input id="aaa" type="text">
```

First name

Visible text label = "First name"

The screenshot shows the Chrome DevTools interface. The left pane displays the DOM tree:

```
<!DOCTYPE html>
<html lang="en">
  <head>...
  <body>
    <label for="aaa">First name</label>
    <input id="aaa" type="text"> == $0
  </body>
</html>
```

The right pane shows the Accessibility panel with the following details:

- Styles, Computed, Layout, Event Listeners, Accessibility tabs.
- Accessibility Tree (disabled).
- ARIA Attributes (disabled).
- Computed Properties section:
 - Name: "First name"
 - aria-labelledby: Not specified
 - aria-label: Not specified
 - From label (for= attribute): label "First name"
 - placeholder: Not specified
 - aria-placeholder: Not specified
 - title: Not specified
- Role: textbox
- Invalid user entry: false
- Focusable: true

A red arrow points from the text "Accessible name = 'First name'" to the "Name: 'First name'" entry in the Accessibility panel. Another red arrow points from the text "Visible text label = 'First name'" to the visible label element in the DOM tree.

It is possible to create an accessible name that is **partially or even entirely different** from the visible text label.

For example, the accessible name could include additional content **before or after the visible text label.**

```
<button>
  <span class="sr-only">Please</span>
  Save
</button>
```

Save

Visible text label = "Save"

Accessible name = "Please Save"

The screenshot shows the Chrome DevTools interface with the 'Elements' tab selected. A red arrow points from the visible text label 'Save' to the 'Accessible name = "Please Save"' annotation. Another red arrow points from the 'Name: "Please Save"' entry in the Accessibility panel to the 'Accessible name = "Please Save"' annotation. The DevTools sidebar on the left shows the HTML structure: <!DOCTYPE html>, <html lang="en">, <head>, <body>, and a <button> element. The Accessibility panel on the right lists 'Computed Properties' and highlights the 'Name' property.

Computed Properties
Name: "Please Save"
aria-labelledby: Not specified
aria-label: Not specified
From label: Not specified
Contents: "Please Save"
title: Not specified
Role: button
Invalid user entry: false
Focusable: true

However, accessible names must match **at least some aspect of the visible text label.**

A mismatch between the visible text label and the accessible name could **cause confusion for some specific types of users.**

For example, some people with mobility issues use speech recognition tools. If the visible text label doesn't match the accessible name in the API, **the control won't respond to their command.**

And some sighted users use screen readers for additional assistance. If the visible text label doesn't match the accessible name, **this could be confusing.**

This mismatch could also be confusing if screen reader users **need to describe aspects of the UI** to sighted users and vice versa.

Any questions or comments?

aria-labelledby

This is where a primary element is **given a label** (another name for an accessible name) by a secondary elements text string.

The `aria-labelledby` attribute is **applied to the primary element**, and the matching ID value is applied to the secondary element.

```
<section aria-labelledby="aaa">
  <h3 id="aaa">Contact details</h3>
</section>
```

Section accessible name: "Contact details"

The secondary element **does not need to be a child** of the primary element.

```
<p id="bbb">Buy Lawn Mower</p>
<button aria-labelledby="bbb">Buy</button>
```

Button accessible name: "Buy Lawn Mower"

More than one label can be applied to the primary element. They need to be space separated values in the **aria-labelledby** attribute.

```
<p id="ccc">Buy Lawn Mower</p>
<button aria-labelledby="ccc ddd">Buy</button>
<p id="ddd">On special</p>
```

Buttons accessible name: "Buy Lawn Mower On specia

Accessing the exercise:

[DEVELOPER EXERCISE: Using aria-labelledby.](#)

aria-label

The `aria-label` attribute is used to provide a label
directly to the element itself.

```
<button aria-label="Close and return">  
  Close  
</button>
```

Buttons accessible name: "Close and return"

Exercise: Using aria-label

DEVELOPER EXERCISE: Adding accessible names.

Accessible descriptions

In some cases, accessible objects may need more than just an accessible name to **provide additional context**.

For example, **help text or error messages** associated with individual form controls.

This additional information is referred to as an
“accessible description” if it is exposed in the
accessibility tree.

Accessible descriptions are **defined as text strings**.

▼ Name: "Address"

aria-labelledby: Not specified

aria-label: Not specified

From label (for= attribute): **label.label** "Address"

placeholder: Not specified

aria-placeholder: Not specified

title: Not specified

Description: "*Include full street address*"

Role: textbox

Invalid user entry: false

Focusable: true

Editable: plaintext

Can set value: true

Multi-line: false

Read-only: false

The accessible description **might or might not** be presented visually on-screen.

Accessible names and descriptions are **two totally separate concepts**. They fill two different slots in the accessibility tree.

aria-describedby

This is where a primary element is **given a description** by a secondary elements text string.

The `aria-describedby` attribute is **applied to the primary element**, and the matching `ID` value is applied to the secondary element.

```
<label for="a">Phone</label>
<input id="a" type="text" aria-describedby="i1">
<p id="i1">Error: Include area code</p>
```

This `<input>` element already **has an accessible name of “Phone”**.

▼ Name: "Phone"
aria-labelledby: Not specified
aria-label: Not specified
From label (for= attribute): **label.label** "Phone"
placeholder: Not specified
aria-placeholder: Not specified
title: Not specified
Description: "*Error: Include area code*"
Role: textbox
Invalid user entry: false
Focusable: true
Focused: true
Editable: plaintext
Can set value: true
Multi-line: false
Read-only: false

However, it will now have an accessible description of
“Error: Include area code” in the accessibility tree.

▼ Name: "Phone"

aria-labelledby: Not specified

aria-label: Not specified

From label (for= attribute): **label.label** "Phone"

placeholder: Not specified

aria-placeholder: Not specified

title: Not specified

Description: "Error: Include area code"

Role: textbox

Invalid user entry: false

Focusable: true

Focused: true

Editable: plaintext

Can set value: true

Multi-line: false

Read-only: false

The **aria-describedby** attribute **cannot provide an accessible name** in the accessibility tree - it is just for descriptions.

Multiple descriptions can be applied to a single element using **aria-describedby**. They are defined using space-separated values.

```
<label for="a">Phone</label>
<p id="hint1">Include an area code</p>
<input id="a" type="text" aria-describedby="hint1"
<p id="error1">Error: Include area code</p>
```

The order that these elements are defined within the aria-describedby value **determines the order in which the descriptions are announced.**

In this case, because `hint1` is defined before `error1` the **accessible description** will be:
“Include an area code Error: Include area code”

▼ Name: "Phone"

aria-labelledby: Not specified

aria-label: Not specified

From label (for= attribute): **label.label** "Phone"

placeholder: Not specified

aria-placeholder: Not specified

title: Not specified

Description: "Include area code Error: Include area code"

Role: **textbox**

Invalid user entry: false

Focusable: true

Focused: true

Editable: plaintext

Can set value: true

Multi-line: false

Read-only: false

Exercise: Adding accessible descriptions

Accessing the exercise:

[DEVELOPER EXERCISE: Adding accessible descriptions.](#)

Which one wins?

So, what happens when you use **multiple methods** to provide an accessible name or description for an element?

Let's look at an example with an `<input>` has **three possible sources** for the accessible name.

```
<!-- An associated label -->  
  
<label for="a">Name</label>  
<input  
  id="a"  
  type="text"  
  aria-label="Full name"  
  placeholder="Add your full name"  
>
```

```
<!-- An aria-label attribute -->

<label for="a">Name</label>
<input
  id="a"
  type="text"
  aria-label="Full name"
  placeholder="Add your full name"
>
```

```
<!-- A placeholder attribute -->

<label for="a">Name</label>
<input
  id="a"
  type="text"
  aria-label="Full name"
  placeholder="Add your full name"
>
```

In examples like this, which of these three sources would **be used to define the accessible name?**

Despite multiple possible sources, **only one accessible name** can be defined and applied for any element.

Accessible names should be **defined in the following order:**

1. If present, use `aria-labelledby`.
2. Otherwise, if present, use `aria-label`.
3. Otherwise, if present, use:
 - The elements content OR
 - The elements `alt` OR
 - Content from `<label>`, `<legend>`, `<caption>`
4. Otherwise, if present, use `title`.
5. Otherwise, if present, use `placeholder`.
6. Otherwise, there is no accessible name.

Always try to use **the most semantic method** to apply accessible names and avoid ARIA solutions where possible.

```
<!-- Button name from text string -->  
<button>Button text</button>
```

```
<!-- Link name from text string -->  
<a href="#">Link text</a>
```

```
<!-- Image name from alt attribute value -->  

```

```
<!-- Input name from label text string -->  
<label for="a">Label text</label>  
<input id="a" type="text">
```

```
<!-- Fieldset name from legend text string -->  
<fieldset>  
  <legend>Legend text</legend>  
</fieldset>
```

```
<!-- Table name from caption text string -->  
<table>  
  <caption>Caption text</caption>  
</table>
```

Accessible descriptions should be **defined in the following order:**

1. If present, use `aria-describedby`.
2. Otherwise, if present, use `title`.
3. Otherwise, there is no accessible description.

The `title` attribute

If there is another accessible name option available, the **title** will move to the accessible description slot.

However, if the **aria-describedby** is present, the **title** will not be used as the description either.

The `title` attribute **should only ever be used** as an accessible name for `<frame>` and `<iframe>` elements.

And, the `title` attribute **should never be used as the accessible description** for elements.

The placeholder attribute

Despite the rules for calculating names, the **placeholder** is used instead of the **title** in most browser/screen reader combinations.

If another accessible name is present, the **placeholder** is **still announced** in most browser/screen reader combinations.

In some browser/screen reader combinations, the **placeholder** is announced **as part of the accessible name**.

In other browser/screen reader combinations, it is announced **as part of the accessible description**.

The `placeholder` should never be used **as the only visible text label or accessible name** for elements.

How names and descriptions are announced

How are the accessible name and description
announced in different screen readers?

Screen readers announce objects within the accessibility tree **in the following order**:

- Accessible name
- Role
- Description, then
- Additional instructions.

Let's use the "Address" <input> again to **see the announcement order** in different screen readers.

Mammals

What are mammals? Classification Definitions McKenna/Bell Molecular

What are mammals?

Mammals are the vertebrates within the class *Mammalia*, a clade of *endothermic amniotes* distinguished from reptiles (including birds) by the possession of a neocortex (a region of the brain), hair, three middle ear bones, and mammary glands. Females of all mammal species nurse their young with milk, secreted from the mammary glands.

[Find out more](#) (1)

Classification

Mammal classification has been through several iterations since Carl Linnaeus initially defined the class. No classification system is universally accepted; McKenna & Bell (1997) and Wilson & Reader (2005) provide useful recent compendiums.^[1] George Gaylord Simpson's "Principles of Classification and a Classification of Mammals" (AMNH Bulletin v. 85, 1945) provides systematics of mammal origins and relationships

▼ Name: "Address"

~~aria_labelledby~~: Not specified

~~aria-label~~: Not specified

From label (for= attribute): ~~label.label~~ "Address"

~~placeholder~~: Not specified

~~aria-placeholder~~: Not specified

~~title~~: Not specified

Description: "Include full street address"

Role: textbox

With VoiceOver on the desktop, **there is a pause** after the accessible name and role are announced.

OSX / VoiceOver / Chrome

- Accessible name: “Address”.
- Role: “Edit text”.
- [Pause].
- Description: “Include full street address”.
- Additional instructions: “You are currently on a text field. To enter text in this field, type”.

Windows / NVDA / Chrome

- Accessible name: “Address”.
- Role: “Edit”.
- Description: “Include full street address”.
- Additional instructions: “Blank”.

Windows / JAWS / Chrome

- Accessible name: “Address”.
- Role: “Edit”.
- Description: “Include full street address”.
- Additional instructions: “Type in text”.
